Assignment - 1

Ruiyanesh Bakhtani

20190802079

(Q1) sort the functions —

Sol

$$4 \lg(\lg n) < 4 \log n < n^{1/2} \lg^4(n) < 5n < n^4 < (\lg n)^{5 \lg n}$$

$$< (\lg)^{\lg n} < n^{n^{1/5}} < 5^n < 5^{5n} < (n/4)^{n/4} < (n)^{n/4} <$$

$$4^{n^4} < 4^{4^n} < 5^{5^n}$$

(Q2) solve the following recurrences using masters theorem.

(1)  $T(n) = 2T(n/4) + 1$

Sol comparing  $2T(n/4)$  with  $aT(n/6)$

$$(n)^{\frac{\log 2}{6}} = n^{\frac{\log 2}{4}} = n^{1/2}$$

Comparing  $n^{1/2}$  with 1  $\therefore n^{1/2} \geq 1$

$$T(n) = \Theta(n^{1/2})$$

(2)  $T(n) = 2T(n/4) + n^{1/2}$

Sol comparing  $2T(n/4)$  with  $aT(n/6)$

$$(n)^{\frac{\log 2}{6}} = (n)^{\frac{\log 2}{4}} = n^{1/2}$$

on comparing  $n^{1/2} = n^{1/2}$

$$\therefore T(n) = \Theta(n^{1/2} \log n)$$

(3)  $T(n) = 7T(n/3) + n^2$

Sol Comparing  $7T(n/3)$  with  $aT(n/b)$

$$n^{\log_6 7} = (n)^{\frac{\log 7}{\log 3}} \approx (n)^{1.77}$$

on comparing  $(n)^{1.77} < (n)^2$

$$\therefore T(n) = \Theta(n^2) \text{ Ans}$$

(4)  $T(n) = 7T(n/2) + n^2$

Sol Comparing  $7T(n/2)$  with  $aT(n/b)$

$$n^{\log_6 7} = (n)^{\frac{\log 7}{\log 2}} \approx (n)^{2.805}$$

On comparing with  $f(n)$   $n^{\log_2 7} > n^2$

$$\therefore T(n) = \Theta(n^{\log_2 7}) \text{ Ans}$$

(5)  $T(n) = T(n-3) + n^2$

Ans Master's theorem can't be applied since  $T(n-3)$  is not in the form  $\Theta(T(n/6))$

(6)  $T(n) = 2T(n/2) + n/\lg n$

Ans Master's theorem can't be applied since  $f(n)$  is not a polynomial ( $n/\lg n$ )

$$\textcircled{2} \quad T(n) = T(n-1) + n/\lg n$$

Ans Master's theorem can't be applied since  $T(n-1)$  is not in the form of  $aT(n/b)$  also  $f(n) = n/\lg n$  which is not a polynomial.

\textcircled{3} Using substitution method show the recurrence

Equation for  $T(n) = 2T(n/2) + O(n)$ . Compute the upper bound and lower bound separately with steps involved.

$$\textcircled{Sol} \quad T(n) = 2T(n/2) + O(n) \quad \textcircled{1}$$

$$T(n/2) = 2T(n/4) + cn/2 \rightarrow \text{sub. in } \textcircled{1}$$

$$T(n) = 2[2T(n/4) + cn/2] + cn$$

$$T(n) = 4T(n/2^2) + cn + cn \quad \textcircled{2}$$

after solving for k steps.

$$T(n) = 2^k T\left(\frac{n}{2^k}\right) + k(cn)$$

assuming  $\frac{n}{2^k} = 1$  for getting  $T(1)$

$$n = 2^k \text{ and } k = \lg n$$

$$T(n) = 2^{\lg n} T\left(\frac{n}{2^{\lg n}}\right) + \lg n (cn)$$

$$T(n) = nT(1) + \log_2(n)$$

assuming  $T(1) = 0$

$$T(n) = cn \log n$$

$$\boxed{T(n) = O(n \log n)}$$

# Upper bound for  $T(n) = 2T(n/2) + O(n)$

$$T(n) \leq 2T(n/2) + cn - \textcircled{1} \quad \text{for some (+)ve const}$$

Given:-  $T(n) \leq dn \log n$  for some (+)ve const  $d$

$$T(n/2) \leq \frac{dn}{2} \log(n/2) \quad \text{substituting in } \textcircled{1}$$

$$T(n) \leq \frac{d}{2} [dn \log(n/2)] + cn$$

$$\leq \frac{d^2 n}{2} \log(n/2) + cn$$

$$\leq dn \log n - dn \log_2 2 + cn$$

$$\leq dn \log n - n(d - c)$$

$$\text{if } (d - c) > 0$$

$$d > c$$

$$T(n) = O(n \log n)$$

(a) Lower bound for  $T(n) = 2T(n/2) + \Theta(n)$

$$T(n) \geq 2T(n/2) + cn - \textcircled{1} \quad \text{for some positive const. } c$$

Answer:  $T(n) \geq dn \log n$  for some const. d.

$$T(n/2) \geq \frac{dn}{2} \log\left(\frac{n}{2}\right) \quad \text{substituting in } \textcircled{1}$$

$$T(n) \geq 2\left[\frac{dn}{2} \log\left(\frac{n}{2}\right)\right] + cn$$

$$\geq dn \log n - dn + cn$$

$$\geq \frac{dn \log n - n(cd-c)}{\text{desired residual}}$$

$$\text{if } d-c < 0 \Rightarrow T(n) = -2(cn \log n)$$

$$c \geq d$$

(Q) Write a short note on Merge sort with an example (with working) write pseudo code for recursive & iterative method. Explain time complexity briefly.

Sol: Merge sort is a divide and conquer algorithm. It divides input array in two halves, calls itself for the two halves and then merges the two sorted halves. The merge function() is used for merging two halves. The merge arr[l..m] and arr[m...r] is key process that assumes that arr[l..m] and arr[m...r] are sorted and merges the two sub-sorted arrays into one.

## \* Working of merge sort →

To understand merge sort we take an unsorted array as following →

|    |    |    |    |   |    |    |    |    |    |
|----|----|----|----|---|----|----|----|----|----|
| 10 | 14 | 28 | 11 | 7 | 16 | 30 | 50 | 25 | 18 |
|----|----|----|----|---|----|----|----|----|----|

We know that merge sort first divides the whole array iteratively into equal halves until individual element array is achieved. We see that an array of 10 elements is divided into arrays of size 5.

|    |    |    |    |   |    |    |    |    |    |
|----|----|----|----|---|----|----|----|----|----|
| 10 | 14 | 28 | 11 | 7 | 16 | 30 | 50 | 25 | 18 |
|----|----|----|----|---|----|----|----|----|----|

This does not change the sequence of appearance of items in the original. Now we divide these 2 arrays into halves.

|    |    |    |    |   |    |    |    |    |    |
|----|----|----|----|---|----|----|----|----|----|
| 10 | 14 | 28 | 11 | 7 | 16 | 30 | 50 | 25 | 18 |
|----|----|----|----|---|----|----|----|----|----|

We further divide these arrays till we achieve atomic value which can be no more divided.

|    |    |    |    |   |    |    |    |    |    |
|----|----|----|----|---|----|----|----|----|----|
| 10 | 14 | 28 | 11 | 7 | 16 | 30 | 50 | 25 | 18 |
|----|----|----|----|---|----|----|----|----|----|

|    |    |    |    |   |    |    |    |    |    |
|----|----|----|----|---|----|----|----|----|----|
| 10 | 14 | 28 | 11 | 7 | 16 | 30 | 50 | 25 | 18 |
|----|----|----|----|---|----|----|----|----|----|

Now, we combine them exactly in the order as they were broken down.

The last broken list was 11, 7 and 25, 18 arranging & merging them.

(28)

|    |    |   |   |    |    |    |    |    |    |
|----|----|---|---|----|----|----|----|----|----|
| 10 | 14 | , | 7 | 11 | 16 | 30 | 50 | 18 | 25 |
|----|----|---|---|----|----|----|----|----|----|

Next we'll compare  $[10, 14]$ ,  $[28, [7, 11]]$ ,  $[16, 30]$ ,  $[50, [18, 25]]$

|    |    |          |    |    |    |    |           |    |    |
|----|----|----------|----|----|----|----|-----------|----|----|
| 10 | 14 | <u>7</u> | 11 | 28 | 16 | 30 | <u>18</u> | 25 | 50 |
|----|----|----------|----|----|----|----|-----------|----|----|

|   |    |    |    |    |    |    |    |    |    |
|---|----|----|----|----|----|----|----|----|----|
| 7 | 10 | 11 | 14 | 28 | 16 | 18 | 25 | 30 | 50 |
|---|----|----|----|----|----|----|----|----|----|

|   |    |    |    |    |    |    |    |    |    |
|---|----|----|----|----|----|----|----|----|----|
| 7 | 10 | 11 | 14 | 16 | 18 | 25 | 28 | 30 | 50 |
|---|----|----|----|----|----|----|----|----|----|

\* Pseudo code for recursive merge sort.

If length of array greater than 1  
 $mid = \text{array length} // 2$

$L = 1^{\text{st}} \text{ sorted array } [ : mid ]$

$R = 2^{\text{nd}} \text{ array } [ mid : ]$

Merge sort( $L, R$ )

$i, j, k = 0$

while ( $L$  and  $R$  have elements)

if  $L[0] > R[0]$

    Add  $L[i=0]$  to ~~arr~~ arr $[k]$

    increment  $i$

else

    Add  $R[j]$  to arr $[k]$

    inc.  $j$

$k += 1$

while  $L$  has elements

    Add  $L[i]$  to arr $[k]$

    inc  $i$  and  $k$

while R has elements:

add R[i] to arr[k]

inc j and k

Return arr

## \* Pseudo code for iterative MergeSort -

size = 1

while size become equal to arr.length -

mid = min of (left + size - 1) and (arr.length - 1)

right = (2 \* size + left - 1, arr.length - 1) if

$2 * size + left - 1 \geq (arr.length - 1)$

$n_1 = mid - left + 1$

$n_2 = right - mid$

$L, L_i = [0] * n_1, [0] * n_2$

for i in range 0,  $n_1$

$L[i] \text{ is } arr[left + i]$

for i in range 0,  $n_2$

$R[i] \text{ is } arr[mid + 1 + i]$

$i, j, k = 0, 0, left$

while  $n_1$  and  $n_2$  have elements

if  $L[i] > R[j]$

add  $R[j]$  to arr[k]

inc j

else :

add  $L[i]$  to arr[k]

inc i

$k += 1$

while  $n_1$  has elements

add  $L[j]$  to  $arr[k]$

inc i and k

while  $n_2$  has elements

add  $R[j]$  to  $arr[k]$

inc j & k

$left \neq left + size * 2$

$size = 2 \times size$

return arr.

Time Complexity of Merge sort

Time complexity can be expressed as following  
recurrence relation:

$$T(n) = 2T(n/2) + O(n)$$

and the solution of the recurrence is  $O(n \log n)$

Time complexity of Merge sort is  $O(n \log n)$  in all 3 cases (worst, average, and best)

Q5) Write pseudo code and explain with example different partition algorithms of quick sort. Explain briefly the time complexity of quick sort.

Sol Pseudo code & exp. of different partition algorithms.

partition ( $A, p, q$ ) #  $A[p \dots q]$

$x \leftarrow A[p]$

$i \leftarrow p[\text{index}]$

for  $j \leftarrow p+1$  to  $q$

if  $A[j] \leq x$

then  $i = i + 1$

exchange  $A[i] \leftrightarrow A[j]$

exchange  $A[p] \leftrightarrow A[i]$

return  $i$

Quick sort ( $A, p, q$ )

if  $p \leq q$

then  $q \leftarrow \text{partition}(A, p, q)$

Quick sort ( $A, p, q-1$ )

Quick sort ( $A, q+1, q$ )

Quick sort ( $A, l, r$ )

# invoking func

Ex arr = [10, 20, 30, 90, 40, 50, 70]

1) define low and high to be 0 and 6

2) and arr[6], i.e. last element to be pivot

define i and j to be 0 and employ <sup>a</sup> lesser for  
i and j

In fi:

3) In first iteration i and j are both 0

∴ no swapping, increment i and j

4) when  $i=1, j=1$

compare arr[j] with pivot

arr[j] > pivot

increment j

5).  $i=1, j=2$  On comparing arr[j] with pivot  
 $arr[j] < \text{pivot}$

swap both

arr = [10, 30, 20, 30, 40, 50, 70]

inc. i, j.

6).  $i=2, j=3$   $arr[j] > \text{pivot}$

increment j, no swapping

④  $i=2, j=4$   $arr[j] < \text{pivot}$

swap both & inc. i, j

arr = [10, 30, 40, 90, 20, 50, 70]

② now  $j = 5$        $\text{arr}[j] \leftarrow \text{pivot}$  swap both  
 ~~$i = 8 = 3$~~       and increase  $i, j$

$$\text{arr} = [10, 30, 40, 50, 80, 90, 70]$$

$j = 6$       Break and swap  $\text{arr}[i]$  with  $\text{arr}[\text{pivot}]$   
 $i = 4$

$$\text{arr} = [10, 30, 40, 50, 70, 90, 80]$$

③ now again set  $i, j = 0$  and pivot value  $\text{arr}[i] = 80$   
and repeat the iteration (using recursion).

Till we achieve  $\text{arr} = [10, 30, 40, 50, 70, 80, 90]$

## # HOARE's Partition Algorithm (Pseudo code)

$x = A[p]$

$i = p - 1$

$j = q + 1$

while True

repeat

$j = j - 1$

until  $A[j] \leq x$

repeat

$i = i + 1$

until  $A[i] > x$

if  $i < j$

exchange  $A[i]$  with  $A[j]$

else

return  $j$

exchange  $A[0]$  with  $A[j]$

Ex:  $100 \quad 250 \quad 25 \quad 800 \quad 65 \quad 360 \quad 5 \quad 480$   
pivot  $\rightarrow i$   $\leftarrow j$

$100 \quad 5 \quad 25 \quad 800 \quad 65 \quad 360 \quad 250 \quad 480$

$100 \quad 5 \quad 25 \quad 65 \quad 800 \quad 360 \quad 250 \quad 480$   
 $\leftarrow p \rightarrow j \approx i$

$65 \quad 5 \quad 25 \quad [100] \quad 800 \quad 360 \quad 250 \quad 480$   
 $\leq 100 \quad \geq 100$

\* Time complexity →

$$T(n) = T(k) + T(n-k-1) + O(n)$$

# Worst case →  $T(n) = T(n-1) + O(n)$

$$T(n) = O(n^2)$$

# Best case →  $T(n) = 2T(n/2) + O(n)$

$$T(n) = O(n \log n)$$

# Average case →

you can when partition puts  $O(n/9)$  elements  
in one set &  $O(8n/9)$  in another set.

$$T(n) = T(n/9) + T(8n/9) + O(n)$$

$$T(n) = O(n \log n)$$
